Object recognition databases

Improvements needed* :

- Multiple object class instances within a single image
- Partial occlusion and truncation
- Size, viewpoint and orientation variations
- High degree of intra-class variability
- Exclude pre-segmented objects

* J. Ponce et al. *Dataset Issues in Object Recognition. Toward Category-Level Object Recognition*, Springer-Verlag Lecture Notes in Computer Science., 2006.

Grozi-120

- Multimedia database of 120 grocery products
- Objects vary in color, size, opacity, shape and rigidity. They are found in different lighting conditions and in presence of clutter and occlusion
- ***In vitro*** and ***in situ*** image representations (for training and testing data respectively)

Grozi-120

In vitro data

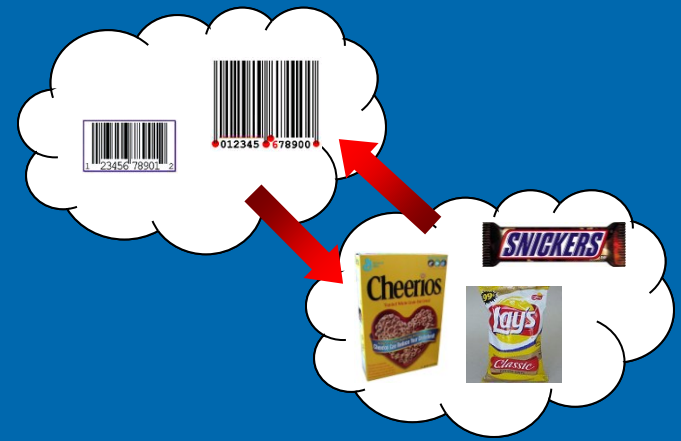

- Isolated images captured under ideal imaging conditions (e.g stock photography studio or lab)
- They can be found in the web (e.g Froogle, Amazon, etc)

Grozi-120

In vitro data

- 676 training images (average 6 images per object)
- Obtained from the web (Froogle, Shopwiki, Amazon Groceries, Yahoo images) using a list of 4000 UPC codes
- Clear foreground–background distinction via binary mask (if desired)

Grozi-120

In situ data

- Images from objects captured in natural environments (real world)
- They were shot inside a grocery store, using a MiniDV camcorder and includes every *in vitro* object
- 29 videos containing all products
- Product location in coordinates saved every 5 frames
- A total of 11194 *in situ* images (average 93 per product)

Experiments

- **Color histogram matching (CHM):**
Histogram template (16 bins in ab from Lab) + integral histogram + L1 distance
- **SIFT: bag of features approach**
One bag per object + L2 distance
- **Boosted Haar-like features (BHaar):**
Data + synthetic data + Haar-like features + cascades (OpenCv)

Experiments

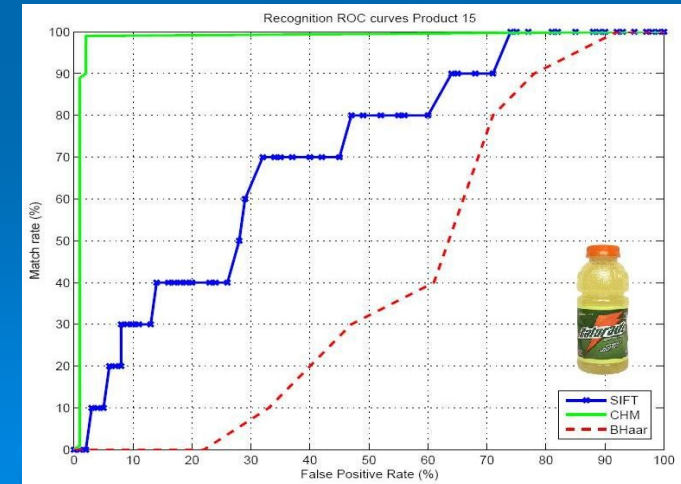

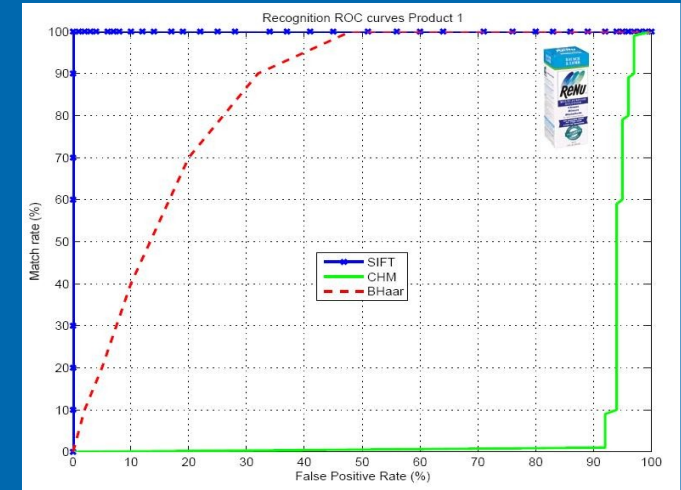

Recognition:

10 *in vitro* samples per object for training (200 for BHaar)

10 *in situ* images per object for testing

Experiments

Localization:

- 10 *in vitro* samples per object for training (200 for BHaar)
- 14 *in situ* frames per object for true positives
- 100 frames with no product on the database as true negatives

Experiments

Conclusions

We presented:

- A new multimedia database for studying object recognition in presence of *in vitro/in situ* dichotomy
- Baseline performances for three widely used algorithms

The results suggest the need of more precise and elaborate recognition algorithms.

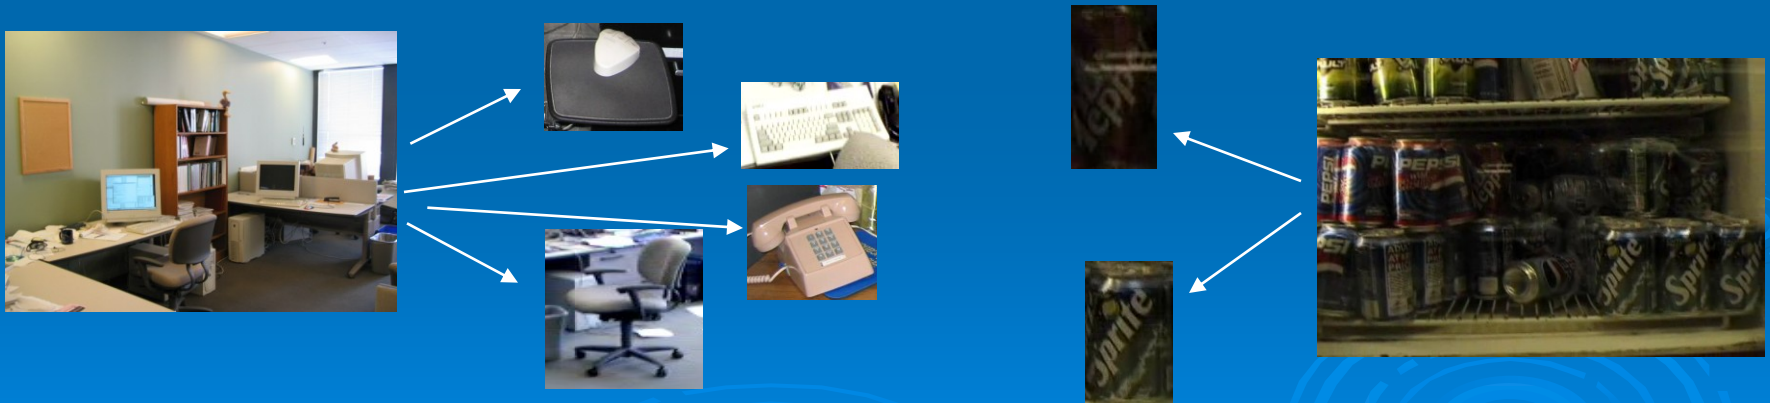

Future Work

- Develop new algorithms that fuse these different approaches in order to improve results

Future Work

- Develop new algorithms that fuse these different approaches in order to improve results
- Make use of context information based on physical object proximity to improve localization of objects in natural scenes

Future Work

- Develop new algorithms that fuse these different approaches in order to improve results
- Make use of context information based on physical object proximity to improve localization of objects in natural scenes
- Use Shared features

Future Work

- Develop new algorithms that fuse these different approaches in order to improve results
- Make use of context information based on physical object proximity to improve localization of objects in natural scenes

- Use Shared features

- Use temporal correlation (tracking)

Future Work

- Develop new algorithms that fuse these different approaches in order to improve results
- Make use of context information based on physical object proximity to improve localization of objects in natural scenes

- Use Shared features

- Use temporal correlation (tracking)
- Include more objects and grow the number of samples per product

Acknowledgments

Part of this work has been funded by the UCSD division of the California Institute for Telecommunications and Information Technology (Calit2) through the 2006 Summer Undergraduate Scholarship Program
