

Fundamentals of Computer Systems

Combinational Logic

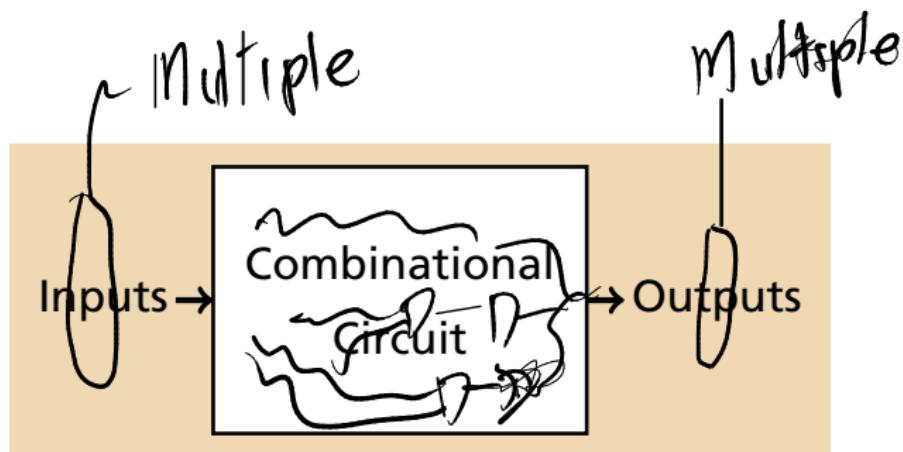

Stephen A. Edwards

Columbia University

Summer 2020

Combinational Circuits

Combinational circuits are stateless.
Their output is a function **only** of the current input.

Basic Combinational Circuits

- Encoders and Decoders
- Priority Encoders
- Multiplexers
- Shifters

Circuit Timing

- Critical Paths and Shortest Paths
- Glitches

Arithmetic Circuits

- Half and Full Adders
- An Adder/Subtractor
- Overflow
- Carry Lookahead Adder

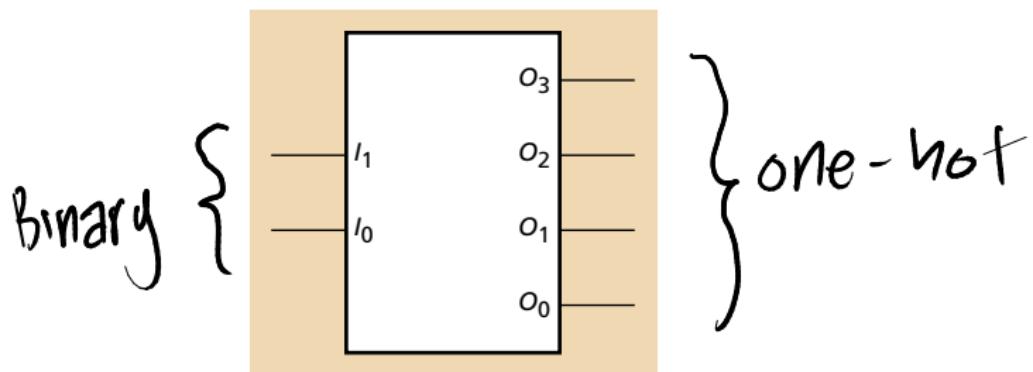

Encoders and Decoders

Overview: Decoder

A decoder takes a n -bit input and produces 2^n single-bit outputs.

The binary input determines which output will be 1, all others 0. This is *one-hot encoding*.

Decoders

2-to-4	
i	out
00	0001
01	0010
10	0100
11	1000

Decoders

Shifters

A shifter shifts the inputs bits to the left or to the right.

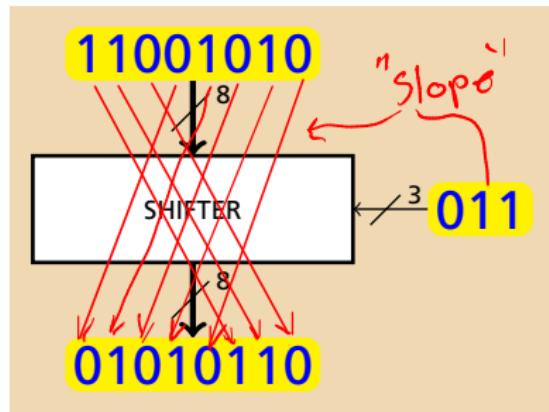

There are various types of shifters.

n -bit left or right

- ▶ Barrel: Selector bits indicate (in binary) how far to the left to shift the input.
- ▶ L/R with enable: Two control bits (upper enables, lower indicates direction).

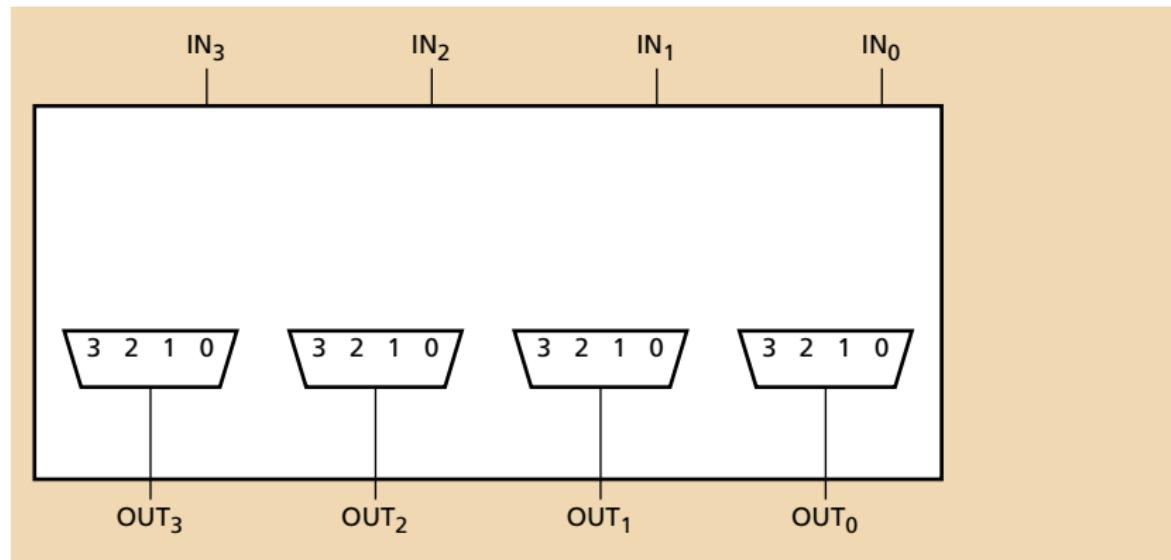

In either case, bits may “roll out” or “wrap around”

Example: Barrel Shifter with Wraparound

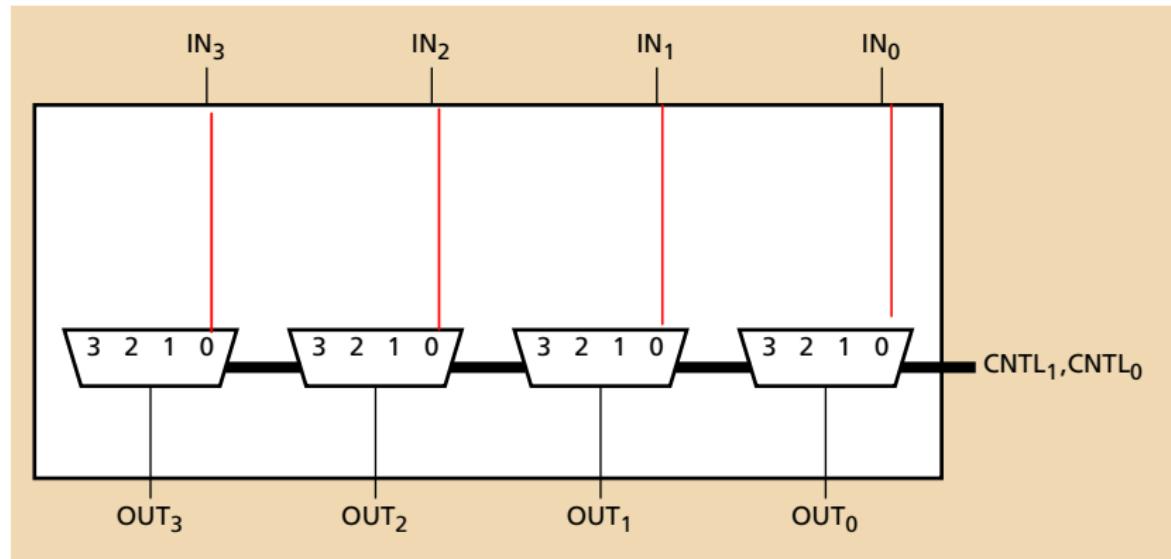

A Barrel Shifter with Wraparound

Main idea: wire up all possible shift amounts and use muxes to select correct one.

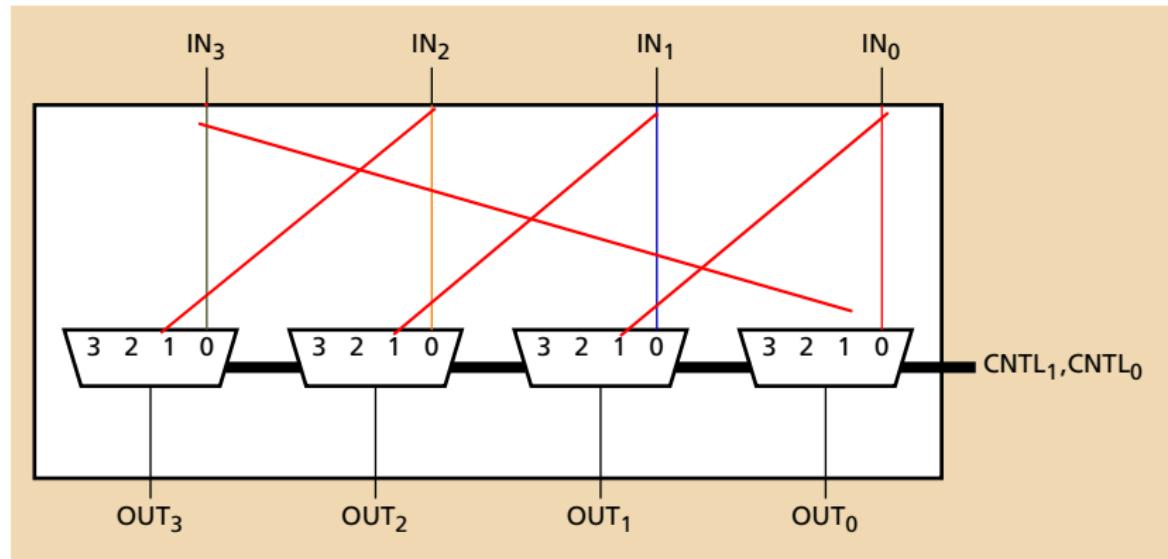

A Barrel Shifter with Wraparound

Main idea: wire up all possible shift amounts and use muxes to select correct one.

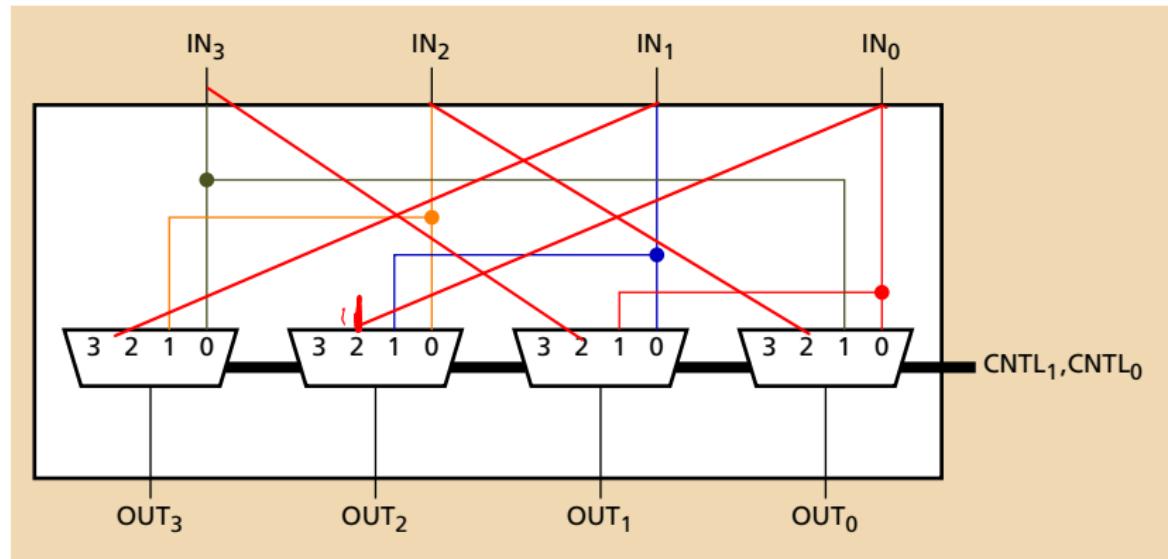

A Barrel Shifter with Wraparound

Main idea: wire up all possible shift amounts and use muxes to select correct one.

Timing

Computation Always Takes Time

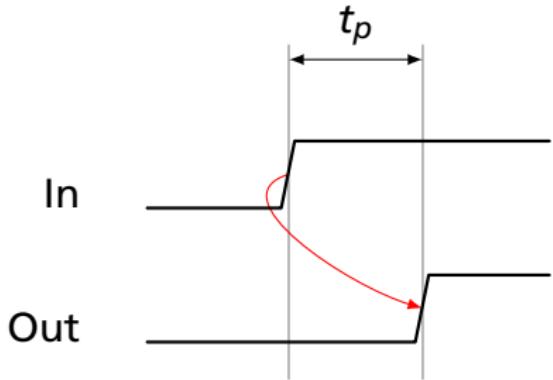

There is always a delay between inputs and outputs because

- ▶ Limited currents charging capacitance
- ▶ The speed of light

The Simplest Timing Model

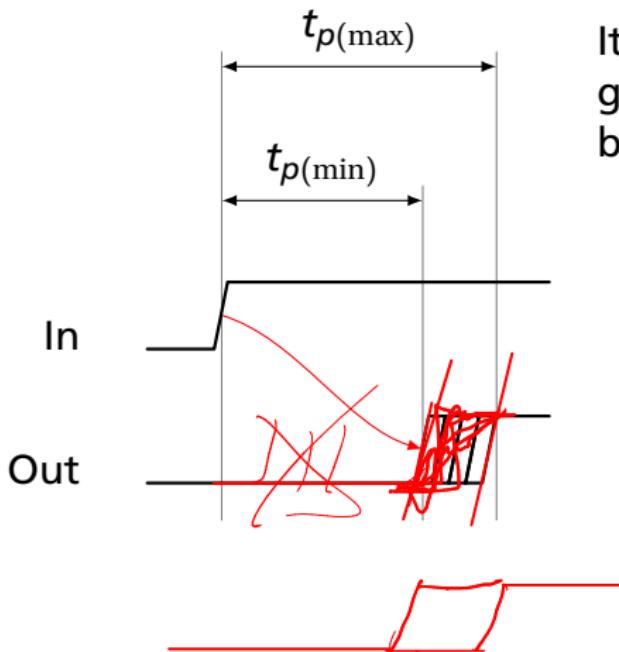

- ▶ Each gate has its own propagation delay t_p .
- ▶ When an input changes, any changing outputs do so after t_p .
- ▶ Wire delay is zero.

1 GHz \sim 1 ns \sim 100s of p⁸

gate \sim 10s of p⁸

A More Realistic Timing Model

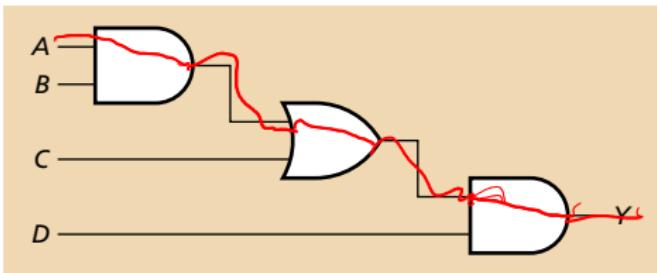

It is difficult to manufacture two gates with the same delay;
better to treat delay as a range.

- ▶ Each gate has a minimum and maximum propagation delay $t_{p(\min)}$ and $t_{p(\max)}$.
- ▶ Outputs may start changing after $t_{p(\min)}$ and stabilize no later than $t_{p(\max)}$.

Critical Paths and Shortest Paths

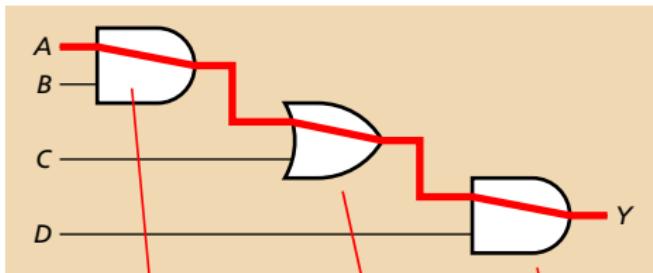

$$t_p = 1 \text{ ns}$$

Three red arrows above the diagram indicate three paths from inputs to output, each labeled 1 ns .

How slow can this be?

Critical Paths and Shortest Paths

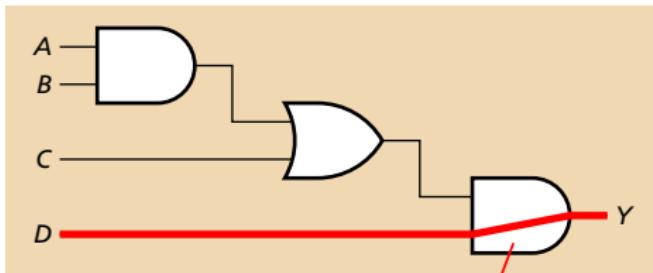

How slow can this be?

The **critical path** has the longest possible delay.

$$t_{p(\max)} = t_{p(\max, \text{AND})} + t_{p(\max, \text{OR})} + t_{p(\max, \text{AND})}$$

Critical Paths and Shortest Paths

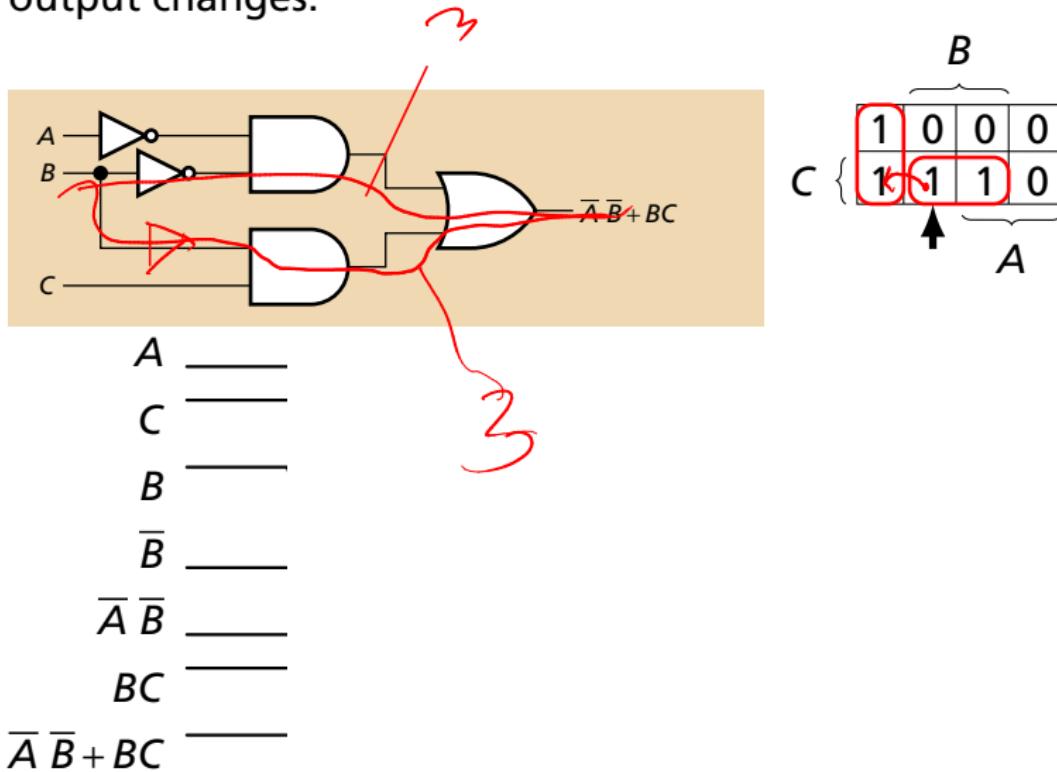

How fast can this be?

The **shortest path** has the least possible delay.

$$t_{p(\min)} = t_{p(\min, \text{AND})}$$

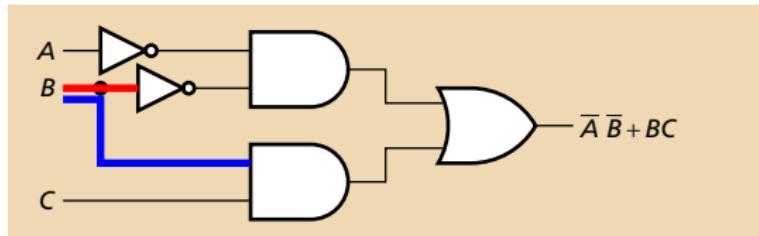

Glitches

A glitch is when a single input change can cause multiple output changes.

Glitches

A glitch is when a single input change can cause multiple output changes.

Glitches

A glitch is when a single input change can cause multiple output changes.

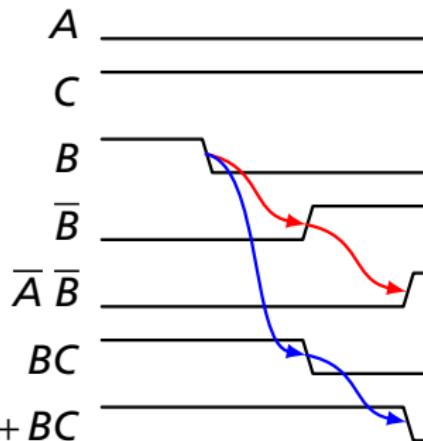

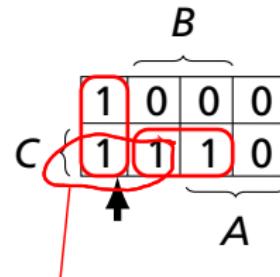

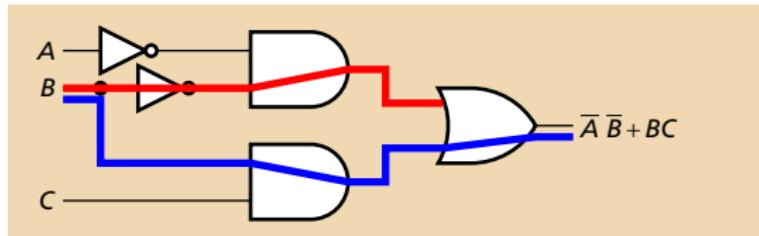

B		0		0	
1		0		0	
1		1		1	
C		{		}	
A		1		1	

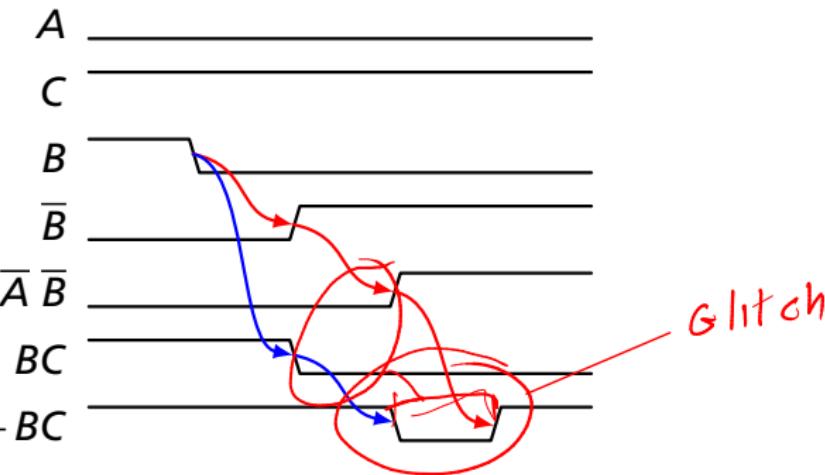

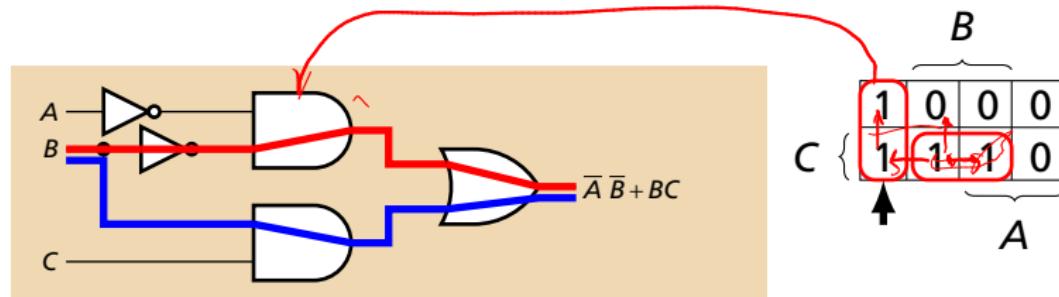

Glitches

A glitch is when a single input change can cause multiple output changes.

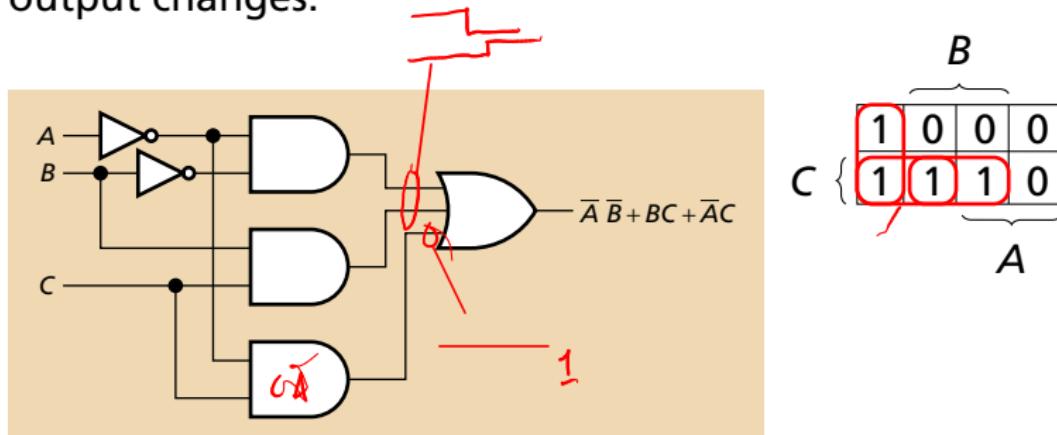

Glitches

A glitch is when a single input change can cause multiple output changes.

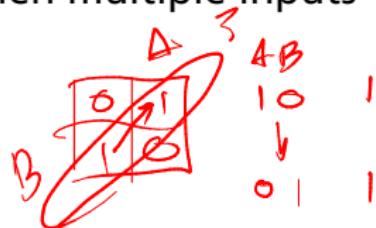

Glitches

A glitch is when a single input change can cause multiple output changes.

Adding such redundancy only works for single input changes; glitches may be unavoidable when multiple inputs change.

Arithmetic Circuits

Arithmetic: Addition

Adding two one-bit numbers:

A and B

Produces a two-bit result:

C S

(carry and sum)

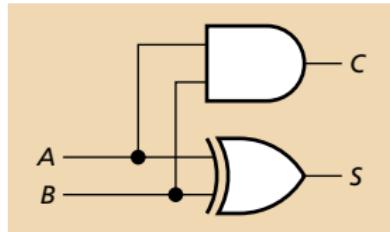

A	B	C	S
0	0	0	0
0	1	0	1
1	0	0	1
1	1	1	0

AB $A \oplus B$

1				

The result does not fit when the top two carry bits differ.

Ripple-Carry Adders are Slow

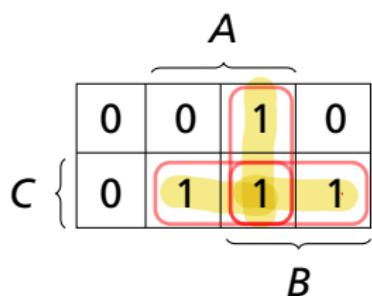

The *depth* of a circuit is the number of gates on a critical path.

This four-bit adder has a depth of 8.

n -bit ripple-carry adders have a depth of $2n$.

Carry Generate and Propagate

The carry chain is the slow part of an adder; carry-lookahead adders reduce its depth using the following trick:

For bit i ,

$$\begin{aligned} C_{i+1} &= A_iB_i + A_iC_i + B_iC_i \\ &= A_iB_i + C_i(A_i + B_i) \\ &= G_i + C_iP_i \end{aligned}$$

"GENERATE" "PROPAGATE"

K-map for the
carry-out
function of a full
adder

Generate $G_i = A_iB_i$ sets carry-out regardless of carry-in.

Propagate $P_i = A_i + B_i$ copies carry-in to carry-out.

Carry Lookahead Adder

Expand the carry functions into sum-of-products form:

$$C_{i+1} = G_i + C_i P_i$$

$$C_1 = G_0 + C_0 P_0$$

$$C_2 = G_1 + C_1 P_1$$

$$= G_1 + (G_0 + C_0 P_0) P_1$$

$$= G_1 + G_0 P_1 + C_0 P_0 P_1$$

$$C_3 = G_2 + C_2 P_2$$

$$= G_2 + (G_1 + G_0 P_1 + C_0 P_0 P_1) P_2$$

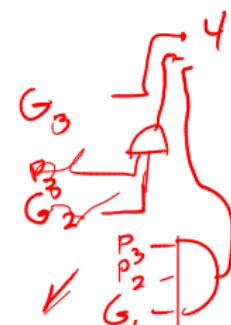

$$= G_2 + G_1 P_2 + G_0 P_1 P_2 + C_0 P_0 P_1 P_2$$

$$C_4 = G_3 + C_3 P_3$$

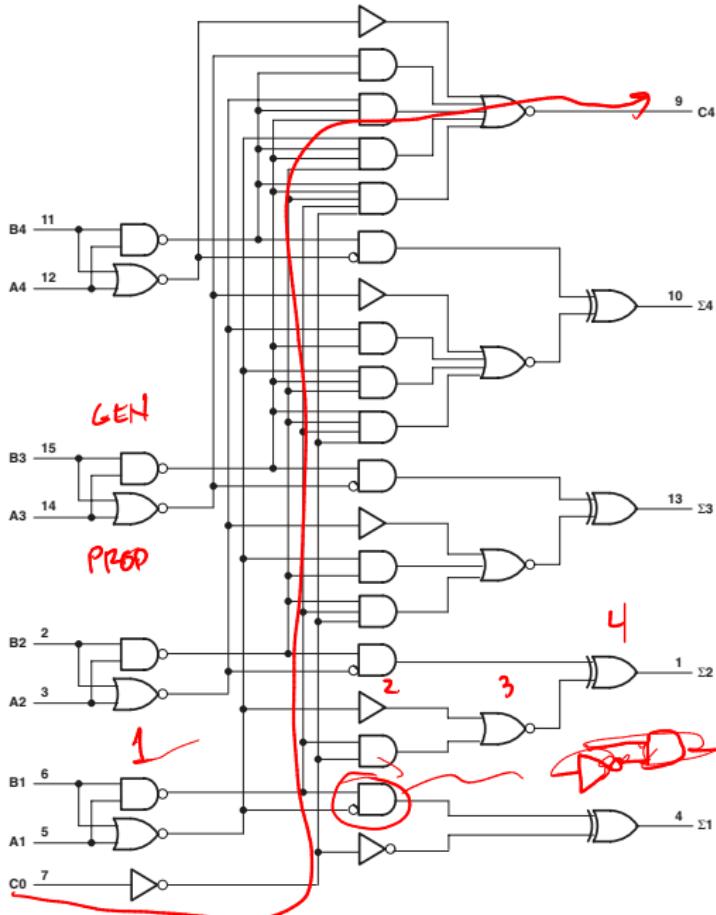

$$= G_3 + (G_2 + G_1 P_2 + G_0 P_1 P_2 + C_0 P_0 P_1 P_2) P_3$$

$$= G_3 + G_2 P_3 + G_1 P_2 P_3 + G_0 P_1 P_2 P_3 + C_0 P_0 P_1 P_2 P_3$$

depth = 2
sum-of-products form

The 74283 Binary Carry-Lookahead Adder

Carry out i has $i + 1$ product terms, largest of which has $i + 1$ literals.

If wide gates don't slow down, delay is independent of number of bits.

More realistic: if limited to two-input gates, depth is $O(\log_2 n)$.
