Patterns

You can define a function with patterns

Patterns may include literals, variables, and _ “wildcard”

```haskell
badCount :: Integral a => a -> String
badCount 1 = "One"
badCount 2 = "Two"
badCount _ = "Many"
```

Patterns are tested in order; put specific first:

```haskell
factorial :: (Eq a, Num a) => a -> a
factorial 0 = 1
factorial n = n * factorial (n - 1)
```
Pattern Matching May Fail

```haskell
Prelude> :{
Prelude|     foo 'a' = "Alpha"
Prelude|     foo 'b' = "Bravo"
Prelude|     foo 'c' = "Charlie"
Prelude| :}
Prelude> :t foo
foo :: Char -> [Char]
Prelude> foo 'a'
"Alpha"
Prelude> foo 'd'
"*** Exception: <interactive>:(23,1)-(25,19): Non-exhaustive patterns in function foo"
```
Let the Compiler Check for Missing Cases

Much better to get a compile-time error than a runtime error:

```haskell
Prelude> :set -Wall
Prelude> :{
Prelude| foo 'a' = "Alpha"
Prelude| foo 'b' = "Bravo"
Prelude| :}

<interactive>:32:1: warning: [-Wincomplete-patterns]
  Pattern match(es) are non-exhaustive
  In an equation for 'foo':
    Patterns not matched: p where p is not one of {'b', 'a'}

Prelude> :set -Wincomplete-patterns
```
Pattern Matching on Tuples

A tuple in a pattern lets you dismantle the tuple. E.g., to implement \( \text{fst} \),

```hs
Prelude> \text{fst}' (x,\_') = x
Prelude> :t \text{fst}'
\text{fst}' :: (a, b) \rightarrow a
Prelude> \text{fst}' (42, 28)
42
Prelude> \text{fst}' ("hello", 42)
"hello"
```

```hs
Prelude> \text{addv} (x1,y1) (x2,y2) = (x1 + x2, y1 + y2)
Prelude> :t \text{addv}
\text{addv} :: (\text{Num} a, \text{Num} b) \rightarrow (a, b) \rightarrow (a, b) \rightarrow (a, b)
Prelude> \text{addv} (1,10) (7,3)
(8,13)
```
Patterns in List Comprehensions

Usually, where you can bind a name, you can use a pattern, e.g., in a list comprehension:

```
Prelude> :set +m
Prelude> pts = [ (a,b,c) | c <- [1..20], b <- [1..c], a <- [1..b],
            a^2 + b^2 == c^2 ]
Prelude> pts
[(3,4,5),(6,8,10),(5,12,13),(9,12,15),(8,15,17),(12,16,20)]
Prelude> perimeters = [ a + b + c | (a,b,c) <- pts ]
Prelude> perimeters
[12,24,30,36,40,48]
```
Pattern Matching On Lists

You can use : and [, , , ]-style expressions in patterns

Like \textit{fst}, \textit{head} is implemented with pattern-matching

Prelude> :{
  Prelude| head' (x:_) = x
  Prelude| head' [] = error "empty list"
  Prelude| :}

Prelude> :t head'
head' :: [p] \rightarrow p

Prelude> head' "Hello"
'H'
Pattern Matching On Lists

```haskell
Prelude> :{
Prelude| dumbLength [] = "empty"
Prelude| dumbLength [_] = "singleton"
Prelude| dumbLength [_,_] = "pair"
Prelude| dumbLength [_,_,_] = "triple"
Prelude| dumbLength _ = "four or more"
Prelude| :}

Prelude> :t dumbLength
dumbLength :: [a] -> [Char]
Prelude> dumbLength []
"empty"
Prelude> dumbLength [1,2,3]
"triple"
Prelude> dumbLength (replicate 10 ' ')
"four or more"
```
List Pattern Matching Is Useful on Strings

```
Prelude> :{
Prelude|   notin ("i":"n":xs) = xs
Prelude|   notin xs = "in" ++ xs
Prelude| :}

Prelude> notin "inconceivable!"
"credible"
Prelude> notin "credible"
"incredible"
```
Pattern Matching On Lists with Recursion

Prelude> :{  
Prelude| length' [] = 0  
Prelude| length' (_:xs) = 1 + length' xs  
Prelude| :}  
Prelude> :t length'  
length' :: Num p => [a] -> p  
Prelude> length' "Hello"  
5

Prelude> :{  
Prelude| sum' [] = 0  
Prelude| sum' (x:xs) = x + sum' xs  
Prelude| :}  
Prelude> sum' [1, 2, 3, 0, 0, 0, 0]  
4321
The "As Pattern" Names Bigger Parts

Syntax: <name>@<pattern>

Prelude> :{
Prelude| initial "" = "Nothing"
Prelude| initial all@(x:_) = "The first letter of " ++ all ++ 
Prelude| " is " ++ [x]
Prelude| }

Prelude> :t initial
initial :: [Char] -> [Char]
Prelude> initial ""
"Nothing"
Prelude> initial "Stephen"
"The first letter of Stephen is S"
Guards: Boolean constraints

Patterns match structure; guards (Boolean expressions after a |) match value

Prelude> :{
  Prelude| heightEval h
  Prelude|   | h < 150 = "You're short"
  Prelude|   | h < 180 = "You're average"
  Prelude|   | otherwise = "You're tall"  -- otherwise = True
  Prelude| :}

Prelude> heightEval 149
"You're short"

Prelude> heightEval 150
"You're average"

Prelude> heightEval 180
"You're tall"
odd and filter are Standard Prelude functions

odd n = n `rem` 2 == 1

filter :: (a -> Bool) -> [a] -> [a]
filter p [] = []
filter p (x:xs) | p x = x : filter p xs
| otherwise = filter p xs

Prelude> filter odd [1..10]
[1,3,5,7,9]
Compare: Returns LT, EQ, or GT

Another Standard Prelude function

\[
x \ `\text{compare}` \ y \\
| \ x < y \quad = \quad \text{LT} \\
| \ x == y \quad = \quad \text{EQ} \\
| \ \text{otherwise} \quad = \quad \text{GT}
\]

Prelude> :t compare
compare :: Ord a => a -> a -> Ordering
Prelude> compare 5 3
GT
Prelude> compare 5 5
EQ
Prelude> compare 5 7
LT
Prelude> 41 \ `\text{compare}` \ 42
LT
Where: Defining Local Names

triangle :: Int -> Int -> Int -> String
triangle a b c
  | a + b < c || b + c < a || a + c < b = "Impossible"
  | a + b == c || a + c == b || b + c == a = "Flat"
  | right = "Right"
  | acute = "Acute"
  | otherwise = "Obtuse"

where
  right = aa + bb == cc || aa + cc == bb || bb + cc == aa
  acute = aa + bb > cc && aa + cc > bb && bb + cc > aa
  sqr x = x * x
  (aa, bb, cc) = (sqr a, sqr b, sqr c)

Order of the where clauses does not matter

Indentation of the where clauses must be consistent

Where blocks are attached to declarations
The Primes Example

primes = filterPrime [2..]
    where filterPrime (p:xs) =
        p : filterPrime [x | x <- xs, x `mod` p /= 0]

[2..] The infinite list [2,3,4,...]
where filterPrime Where clause defining filterPrime
(p:xs) Pattern matching on head and tail of list
p : filterPrime ... Recursive function application
[x | x <- xs, x `mod` p /= 0] List comprehension: everything in xs not divisible by p
Internally, the Haskell compiler interprets

```
a = b + c
    where
        b = 3
        c = 2
```

as

```
a = b + c  where  {  b = 3 ;  c = 2  }
```

The only effect of layout is to insert `{ ; } tokens. Manually inserting `{ ; } overrides the layout rules
Haskell Layout Syntax

- Layout blocks begin after *let*, *where*, *do*, and *of* unless there’s a `{.
- The first token after the keyword sets the indentation of the block.
- Every following line at that indentation gets a leading `;`
- Every line indented more is part of the previous line.
- The block ends (an implicit `}`) when anything is indented less.

```
a = b + c where
  b = 2
  c = 3

a = b + c
  where b = 2
  c = 3

a = b + c
  where b = 3
      + 2  -- No
  c = 3

a = b + c
  where b = 2
      + 2
  c = 3  -- No
```
Let Bindings: Naming Things In an Expression

```
let <bindings> in <expression>
```

cylinder :: RealFloat a => a -> a -> a
cylinder r h = let sideArea = 2 * pi * r * h
topArea = pi * r^2
    in sideArea + 2 * topArea

This example can be written “more mathematically” with where

cylinder :: RealFloat a => a -> a -> a
cylinder r h = sideArea + 2 * topArea
    where sideArea = 2 * pi * r * h
           topArea = pi * r^2

Semantically equivalent; let...in is an expression; where only comes after bindings. Only where works across guards.
A contrived example:

```plaintext
f a = a + let a = 3 in a
```

This is the “add 3” function. The scope of \( a = 3 \) is limited to the `let...in`

`let` bindings are recursive. E.g.,

```plaintext
let a = a + 1 in a
```

does not terminate because all the \( a \)’s refer to the same thing: \( a + 1 \)

This can be used to define infinite lists

```plaintext
Prelude> take 5 (let x = 1 : 2 : x in x)
[1,2,1,2,1]
```

but is mostly for defining recursive functions. There’s no non-recursive `let`
Let Can Also Be Used in List Comprehensions

Prelude> handshakes n = [ handshakes | a <- [1..n-1], b <- [a+1..n],
                          let handshake = (a,b) ]
Prelude> handshakes 3
[(1,2),(1,3),(2,3)]

Its scope includes everything after the \textit{let} and the result expression
case...of Is a Pattern-Matching Expression

Defining a function with patterns is syntactic sugar for case...of

badCount 1 = "One"
badCount 2 = "Two"
badCount _ = "Many"

is equivalent to

badCount x = case x of
1 -> "One"
2 -> "Two"
_ -> "Many"

But, like let, case...of is an expression and may be used as such:

describeList :: [a] -> String
describeList xs = "The list is " ++ case xs of
  [] -> "empty"
  [x] -> "a singleton"
  _  -> "two or more"
