1. The Fisher metric on the n-simplex corresponding to the n+1 dimensional multinomial

\[ p(x|\theta) = \frac{\left(\sum_{i=1}^{n+1} x_i\right)!}{x_1!x_2! \ldots x_{n+1}!} \theta_1^{x_1}\theta_2^{x_2}\ldots\theta_{n+1}^{x_{n+1}} \] (1)

is

\[ g_{ij} = \sum_{k=1}^{n+1} \frac{1}{\theta_k} (\partial_i \theta_k) (\partial_j \theta_k). \] (2)

Note that i and j are indices in some unspecified local coordinate system and have nothing to do with the other index k. Differentiation w.r.t to the corresponding coordinates is denoted \( \partial_i \) and \( \partial_j \) and is assumed to apply to the immediately following symbol only.

To derive (2), the key step is to rewrite the Fisher metric

\[ g_{ij} = \int (\partial_i \log p(x|\theta)) (\partial_j \log p(x|\theta)) p(x|\theta) \, dx \] (3)
as

\[ g_{ij} = -\int (\partial_j \partial_i \log p(x|\theta)) p(x|\theta) \, dx = -E[\partial_j \partial_i \log p(x|\theta)] \] (4)

To see the equivalence of (3) and (4) note that the latter is equal to

\[ -\int \left( \frac{\partial_j \partial_i p(x|\theta)}{p(x|\theta)} - \frac{\partial_j p(x|\theta) \partial_i p(x|\theta)}{(p(x|\theta))^2} \right) p(x|\theta) \, dx \]

where the first term vanishes because \( \int p(x|\theta) \, dx = 1 \) is a constant. The second term gives exactly (3) by \( \partial_i \log p(x|\theta) = (\partial_i p(x|\theta))/p(x|\theta) \).

We may now compute

\[ \partial_j \partial_i \log p(x|\theta) = \sum_{k=1}^{n+1} \partial_j \left( \partial_i \theta_k \frac{\partial \log p(x|\theta)}{\partial \theta_k} \right) = \sum_{k=1}^{n+1} \partial_j \left( \partial_i \theta_k \frac{x_k}{\theta_k} \right) = \sum_{k=1}^{n+1} \partial_j \partial_i \theta_k \frac{x_k}{\theta_k} - \sum_{k=1}^{n+1} \partial_i \theta_k \partial_j \theta_k \frac{x_k}{\theta_k} \]
and plug it into (4), noting that $E[x_k] = N\theta_k$ where $N = \sum_{k=1}^{n+1} x_i$:

$$g_{ij} = -E[\partial_j \partial_i \log p(x|\theta)] = -\sum_{k=1}^{n+1} \partial_j \partial_i E[x_k] + \sum_{k=1}^{n+1} \partial_j \theta_k \partial_i \theta_k \frac{E[x_k]}{\theta_k^2} =$$

$$-N \partial_i \partial_j \sum_{k=1}^{n+1} \theta_k + N \sum_{k=1}^{n+1} \partial_i \theta_k \partial_j \theta_k \frac{1}{\theta_k} = N \sum_{k=1}^{n+1} \frac{1}{\theta_k} \partial_i \theta_k \partial_j \theta_k .$$

Up to the constant $N$, which can be ignored, this gives (2).

2.

The metric (2) on the $n$-simplex is the pull-back of the natural metric (inherited from the embedding space) on the positive quadrant of the $n$-sphere related to the simplex by $\theta \mapsto \omega$ by $\theta = \sqrt{\omega}$.

Let $e_1, e_2, \ldots, e_{n+1}$ be the extension of the basis of the local tangent space (the one that the indices in $\partial_i$ and $\partial_j$ refer to) to the embedding space. Any vector $z = \sum_{k=1}^{n+1} \alpha_k \omega_k$ can be expressed in this basis as $z = \sum_{i=1}^{n+1} \beta_i e_i$, with $\alpha_k = \sum_{i=1}^{n+1} \beta_i \partial_i \omega_k$. To recover the natural norm $\|z\|^2 = \sum_{k=1}^{n+1} \alpha_k^2$, we write

$$\|z\| = \sum_{k=1}^{n+1} \sum_{i=1}^{n+1} \sum_{j=1}^{n+1} \beta_i \beta_j \partial_i \omega_k \partial_j \omega_k = z^T G z$$

where $z = (\alpha_1, \alpha_2, \ldots, \alpha_{n+1})$ is the vector form of $z$ in our coordinate system and $G$ is the metric tensor in the same coordinate system with entries

$$G_{i,j} = \sum_{k=1}^{n+1} \partial_i \omega_k \partial_j \omega_k .$$

This (or rather its restriction to the tangent space) is the metric that the sphere inherits from the embedding space. It is now just a matter of applying the chain rule to show that the pull-back of this is the multinomial metric on the $n$-simplex:

$$\sum_{k=1}^{n+1} \partial_i \omega_k \partial_j \omega_k = \sum_{k=1}^{n+1} \left( \partial_i \theta_k \frac{\partial \omega_k}{\partial \theta_k} \right) \left( \partial_j \theta_k \frac{\partial \omega_k}{\partial \theta_k} \right) = \sum_{k=1}^{n+1} \frac{1}{\theta_k} \partial_i \theta_k \partial_j \theta_k .$$
